Managing Early Laryngeal and Hypopharyngeal Cancer

Dr Jeeve Kanagalingam
MA (Cambridge), BM BCh (Oxford), DLO, DOHNS, FRCS (ORL-HNS), FAMS

Consultant ENT / Head and Neck Surgeon
Tan Tock Seng Hospital

Adj Asst Professor in Otolaryngology
Lee Kong Chian School of Medicine
Early cancers?

• Early laryngeal cancers present with hoarseness
  - Lymphatic drainage is poor so ‘occult metastatic’ rate is low
  - Larynx is a complex organ critical to speech and swallowing
  - Preservation of function is important

• Hypopharyngeal cancers grow silently and present late
  - Lymphatic drainage to retropharyngeal plexus of nodes is rich
  - It is largely a simple conduit to the passage of food
  - Preservation of form is important
Larynx cancer in Peninsular Malaysia

The ASR for hypopharyngeal cancer is 0.2 in both sexes
Indians have highest rate at 0.8
Organ preservation diminishes survival

Laryngeal Cancer in the United States: Changes in Demographics, Patterns of Care, and Survival

Henry T. Hoffman, MD, MS, FACS; Kimberly Porter, MPH; Lucy H. Karnell, PhD; Jay S. Cooper, MD; Randall S. Weber, MD; Corey J. Langer, MD; Kie-Kian Ang, MD, PhD; Greer Gay, PhD; Andrew Stewart, MA; Robert A. Robinson, MD, PhD

Background: Survival has decreased among patients with laryngeal cancer during the past 2 decades in the United States. During this same period, there has been an increase in the nonsurgical treatment of laryngeal cancer. Objective: The objectives of this study were to identify trends in the demographics, management, and outcome of laryngeal cancer in the United States and to analyze factors contributing to the decreased survival. Study Design: The authors conducted a retrospective, longitudinal study of laryngeal cancer cases. Methods: Review of the National Cancer Data Base (NCDB) revealed 158,496 cases of glottic cancers classified as T3N0M0. Initial treatment of T3N0M0 laryngeal cancer (all sites) in the 1994 to 1996 period resulted in poor 5-year relative survival for those receiving either chemoradiation (59.2%) or irradiation alone (42.7%) when compared with that of patients after surgery with irradiation (65.2%) and surgery alone (63.3%). In contrast, identical 5-year relative survival (65.6%) rates were observed during this same period for the subset of T3N0M0 glottic cancers initially treated with either chemoradiation or surgery with irradiation. Conclusions: The decreased survival recorded for patients with laryngeal cancer...
Organ preservation diminishes survival
Meticulous assessment is important

- History, focus on symptoms of dysphonia, dyspnoea, stridor, dysphagia, aspiration, pain
- Office examination
  - Larynx / Pharynx
  - Neck
- Panendoscopy & ELMs
- Imaging
Panendoscopy and ELMs

- Neck and oral palpation. Assess tongue base
- Rigid oesophagoscopy
  - Turn scope to allow for examination of pyriform fossae
- ELMs with photos
  - 0, and angled 30 and 70 degree telescopes
  - Subglottic extension
Regions of the larynx

• Supraglottis
  – 5 parts: suprahyoid and infrahyoid epiglottis, false cords, aryepiglottic folds, arytenoids

• Glottis
  – True vocal cords, floor of ventricle and region 5 mm below true vocal cords or 1 cm below lateral border of ventricle
  – 3 parts: true cords, anterior commissure and ventricle

• Subglottis
  – Region beyond 5 mm below true vocal cords or 1 cm below lateral border of ventricle to lower border of cricoid ring
<table>

</table>
| **T2**   | Tumour extends to supraglottis and/or subglottis with normal vocal cord mobility  
|          | T2a. Tumour extends to supraglottis and/or subglottis with normal vocal cord mobility  
|          | T2b. Tumour extends to supraglottis and/or subglottis with impaired vocal cord mobility  |
| **T3**   | Tumour extends to larynx with vocal cord fixation and/or invades paraglottic space, and/or with minor thyroid cartilage erosion (e.g., inner cortex) |
| **T4a**  | Tumour involves thyroid cartilage, or invades tissues beyond the larynx, e.g., trachea, soft tissues of neck including deep/extrinsic muscle of tongue (genioglossus, hyoglossus, palatoglossus, and styloglossus), strap muscles, thyroid, oesophagus |
Imaging

- Contrast-enhanced CT of the larynx and thorax for all patients
- No need for bone scans / liver ultrasound
- MRI is fast becoming modality of choice but problems with
  - Movement artefact
  - Cost
- For the hypopharynx, MR is modality of choice (Royal College of Radiologists, UK)
Early hypopharyngeal cancers often missed on CT
Early hypopharyngeal cancers often missed on CT

Early hypopharyngeal cancers often missed on CT
Early hypopharyngeal cancers often missed on CT
Early hypopharyngeal cancers often missed on CT
Careful examine the hypopharynx

- Sit patient up in the ‘sniffing the air’ position
- Valsalva or whistle to open up the pharynx
- Observe for any pooling
- Transnasal oesophagoscopy can be useful
HPV and laryngeal cancer?

• Retrospective study in Detroit
• Up to 27%
• Appears to have no effect on survival
Figure 8–2. A, Sagittal section of larynx demonstrating the preepiglottic and B, coronal section of larynx demonstrating the paraglottic space.
Treatment

- Glottic
- Supraglottic
- Subglottic
Glottic - early stage (T1-2a)

- T1-T2 disease should be treated with either radiation or larynx preserving surgery (transoral laser or open partial laryngeal surgery)
- Surgery should be with the aim of achieving clear margins
- Avoid combined modality therapy
- Usual RT is 50-52 Gy in 16# or 53-55 Gy in 20#
- No need for elective treatment of nodes
- Local control rates for T1a (90-93%) and T1b (85-89%) at 5 years
Larynx-preserving surgery

- Transoral Laser
- Vertical Partial Hemilaryngectomy
- Fronto-lateral Partial Hemilaryngectomy
- Supraglottic Laryngectomy
- Supracricoid Laryngectomy + CHP / CHEP
Transoral Laser Surgery

- Utilises Carbon Dioxide laser beam to resect tumour
- Offers a quick alternative to radiotherapy
- Is organ sparing
- Useful in managing laryngeal recurrence
Results of 333 cases of vocal cord carcinomas pT1a (1979 - 2001)

Tumor extent: more than 1/3 of the vocal cord: 68%; anterior commissure involvement: 22%; only midcordal lesion: 14%.

Complication rate: 1.2% (postoperative hemorrhage 2, edema 2; no tracheostomy, no feeding tube

Median follow-up: 72 months

DIAGNOSIS
A. LEFT VOCAL CORD TUMOUR:
* MODERATELY DIFFERENTIATED SQUAMOUS CELL CARCINOMA
* <0.5MM FROM THE DEEP MARGIN FOCALLY

B. ANTERIOR MARGIN, LEFT VOCAL CORD: NEGATIVE FOR MALIGNANCY

C. MIDDLE MARGIN, LEFT VOCAL CORD: NEGATIVE FOR MALIGNANCY

D. POSTERIOR MARGIN, LEFT VOCAL CORD: NEGATIVE FOR MALIGNANCY

E. LEFT VENTRICLE OF LEFT VOCAL CORD: NEGATIVE FOR MALIGNANCY

F. ANTERIOR COMMISURE, LEFT VOCAL CORD: NEGATIVE FOR MALIGNANCY

Video 6

Supracricoid laryngectomy
Supraglottic - early stage

- T1-T2 disease should be treated with either radiation or larynx preserving surgery (transoral laser or supraglottic laryngectomy)
- Due to rich lymphatic supply elective treatment of the node-negative neck bilaterally is necessary
Thank You
